

Electron Configuration – an “address” for the electrons in an atom

An Orbital is:

How do we describe orbitals?

- 1.
- 2.
- 3.
- 4.

Different orbitals are in different energy levels

Different orbitals have different shapes

Different orbitals have different orientations

Each orbital is only allowed to have two e⁻s

Where do e⁻ live? What is the address for one?

State -----> Energy level

City -----> Type/shape of orbital

Street -----> Orientation or orbital

House # -----> Spin up or spin down of electron

Electron configuration for an electron in the second energy level, inside a p shaped orbital that is lined up on the x axis and is a spin up electron:

They can get REALLY long

$1s_{+\frac{1}{2}}, 1s_{-\frac{1}{2}}, 2s_{+\frac{1}{2}}, 2s_{-\frac{1}{2}}$

$2p_{x+\frac{1}{2}}, 2p_{x-\frac{1}{2}}, 2p_{y+\frac{1}{2}}$

$2p_{y-\frac{1}{2}}, 2p_{z+\frac{1}{2}}, 2p_{z-\frac{1}{2}}$

Want to describe where ALL the e⁻ in an atom were? Shrink it down and only list:

- 1.
- 2.
- 3.

Example:

Steps to finding all the electrons

1. Pick an _____
2. Find the number of _____
3. Start putting electrons into the _____ Use an _____
4. List which _____ you used and _____ electrons in each one

Rules for putting electrons in an orbital diagram:

1. Aufbau Principle

An electron occupies the lowest energy orbital that it can.

Means:

2. Pauli Exclusion Principle

No two e⁻s in the same atom can have the same set of 4 quantum numbers

Means:

3. Hunds Rule

Orbitals of equal energy are each occupied by one e⁻ before any orbital is occupied by a second e⁻.

Means:
